Chapter 2

Solutions to selected exercises:

2.1-1

$$A = [31, 41, 59, 26, 41]$$
$$A = [31, 41, 59, 26, 41]$$
$$A = [31, 41, 26, 59, 41]$$
$$A = [31, 26, 41, 59, 41]$$
$$A = [26, 31, 41, 59, 41]$$
$$A = [26, 31, 41, 41, 59]$$

Algorithm 1 BinaryAddition(A,B,n)
2.1-4

$carry \leftarrow 0$
for $i \leftarrow 1$ to n: **do**
    $C[i] \leftarrow (A[i] + B[i] + C[i]) \, mod \, 2$
    $carry \leftarrow A[i] * B[i]$
end for
$C[i+1] \leftarrow carry$
return C

- Input: two n-bit numbers A, B.

- Output: the sum of A, B - an $n + 1$-bit number.

2.2-3   Define $X =$ The number of elements checked in a "brute force" linear search.

Than $X \in \{1...n\}$ and the average number of elements checked in a linear search is exactly:

$$E[X] = \sum_{i=1}^{n} \frac{1}{n} i = \frac{1}{n} \sum_{i=1}^{n} i = \frac{n(n-1)}{2n} = \Theta(n)$$

The worst case is where the last element of the array is the one searched for - resulting in an $\Theta(n)$ run time.

2.3-3

$$T(n) = \begin{cases} 2 & n = 2 \\ 2T(\frac{n}{2}) + n & n > 2 \end{cases}$$

Q: Proof by induction that if n is an exact power of two (that is $n = 2^k$ for some constant $k \geq 1$) than $T(n) = nlogn$.

Proof: By induction.

Base case: for $k = 1$ than $T(n) = 2 = 2log2 = nlogn$
Assumption: Assume the above holds for all integers up to $k > 1$.
Induction step: We now prove the statement for $n = 2^{k+1}$.
Plugging in to the formula

$$T(n) = 2T(\frac{n}{2}) + n = 2T(\frac{2^{k+1}}{2}) + 2^{k+1}$$
$$= 2T(2^k) + 2^{k+1} = 2 * 2^k log2^k + 2^{k+1}$$
$$= k2^{k+1} + 2^{k+1} = (k+1)2^{k+1} = 2^{k+1}log2^{k+1}$$
$$= nlogn$$

$\square$

Algorithm 2 BinarySearch(A,x)

$l \leftarrow 0$
$r \leftarrow length(A)$
while $l < r - 1$ **do**
  if $x = A[\frac{l+r}{2}]$ **then**
    $\frac{l+r}{2}$
  end if
  if $x > A[\frac{l+r}{2}]$ **then**
    $l = A[\frac{l+r}{2}]$
  else
    $r = A[\frac{l+r}{2}]$
  end if
end while
return -1

At each iteration of the while loop the distance between the two pointers - l, r - is halfed until the element is found or we return -1. The while loop will terminate once the two pointers are at distance two at which point either the element x is found or the loop will terminate. Thus the distance between the two pointers at each iteration i is percisly $\frac{length(A)}{2^i} = \frac{n}{2^i}$

At the time of the termination the distance between the two pointers is two, thus -

$$\frac{n}{2^i} = 2$$
$$n = 2^{i+1}$$
$$log(n) = i + 1$$
$$log(n) - 1 = i$$
$$\Theta(log(n)) = i$$

Algorithm 3 FindSum(A,x)

$B \leftarrow MergeSort(A)$
$l \leftarrow 0$
$r \leftarrow length(B)$
while $l < r$ **do**
  if $B[l] + B[r] == x$ **then**
    return true
  else if $B[l] + B[r] < x$ **then**
    $l \leftarrow l + 1$
  else
    $r \leftarrow r - 1$
  end if
end while
return false

---

a   Given $\frac{n}{k}$ lists each of size k. Applying *InsertionSort* to each list seperately yealds worst-case runtime of $\Theta(k^2)$. Doing this for all $\frac{n}{k}$ lists yealds an $\Theta(\frac{n}{k}k^2) = \Theta(nk)$ runtime algorithm.

b

Algorithm 4 ModifiedMergeSort(A)

Split A to form $S = [A_1, .., A_{\frac{n}{k}}]$ array of sub-arrays of size k
for $i \leftarrow 1$ to $\frac{n}{k}$ **do**
  $A_i \leftarrow InsertionSort(A_i)$
end for
while $|S| > 1$ **do**
  $l \leftarrow 1$
  $r \leftarrow length(S)$
  $S' \leftarrow \Phi$
  while $l < r$ **do**
    $S' \leftarrow S' \bigcup Merge(A_l, A_r)$
    $l \leftarrow l + 1$
    $r \leftarrow r - 1$
  end while
  $S \leftarrow S'$
end while

We prove that at each iteration of the outer while loop the size of $|S|$ is $\frac{n}{2^i k}$.
Proof: By induction,

Base $i = 1$: In the first iteration we set l and r to hold the two opposit ends of S, at each iteration we merge two subsets and continue so on until $l = r$ or $l > r$ (depending on the number of subsets) because at each iteration we merged two subsets the number of iterations of the inner loop is percisly $\frac{n}{2k}$.

Step: Assume that the number of subsets in $|S|$ is $\frac{n}{2^i k}$ at iteration i next we prove that at iteration $i + 1$ the above statement holds.

Again, from the same argument for the base case - at each iteration of the inner loop the number of elements decrease by two the number of iterations of the inner loop is $\frac{n}{2^{i+1}k}$ yeilding that number of subsets.

The outer loop will terminate once $|S| = 1$, that is -

$$\frac{n}{2^i k} = 1$$
$$\frac{n}{k} = 2^i$$
$$log(\frac{n}{k}) = i$$

At each iteration we perform $\frac{n}{2^i k}$ merges each runs in $\Theta(2^i k)$ for a total of $\Theta(n)$, Thus the total running time of the while loop is $\Theta(nlog(\frac{n}{k}))$

All together we get $\Theta(nlog(\frac{n}{k}) + nk)$.

c   If one chooses $k = 1$ we get percisly $MergeSort$.

If one chooses $k = n$ we get percisly $InsertionSort$, Thus the choice of k needs to be as close as possible to one. If we choose $k = \Theta(1 - \frac{1}{n}) = \Theta(\frac{n-1}{n})$ which asymptotically is close to one we get -

$$T(n) = \frac{n(n-1)}{n} + nlog(\frac{n}{\frac{n-1}{n}})$$
$$= n - 1 + nlog(\frac{n^2}{n-1})$$
$$\approx \Theta(nlogn)$$

d   In practice one can simply use $MergeSort$ or if one had to use the modified version, use smaller values of k checking these values "brute force".

2-4

a   The inversions of $[2, 3, 8, 6, 1]$ are

$$(8, 6), (8, 1), (6, 1), (3, 1), (2, 1)$$

b   The permutation τ of the set $\{1, .., n\}$ with the most inversions is $[n, n-1, n-2, ..., 1]$ it has $(n-1) + (n-2) + ... + 1 = \frac{n(n-1)}{2} = \Theta(n^2)$ inversions.

c   We prove the following statement (x, y) is in the set of inversions of $S \iff$ its is switched in some iteration of the while loop in the $InsertionsSort$ algorithm.

$\Longleftarrow$ The pair $(x, y) = (A[i], A[j])$ is switched in some iteration of the *InsertionSort* algorithm, therefor by the loop definition $j = i + 1$ and $y < x$, therefor (x, y) is in the inversions set.

$\Longrightarrow (x, y) = (A[i], A[j])$ are in the inversion set of A. we will prove the following Lemma:

Lemma: if $(x, y) = (A[i], A[j])$ are in the inversion set of A than for any integer $i < k \leq j$ the element $A[k]$ is also in the inversion set.

Proof: by induction on the distance between i and j.

Base: $j - i = 1$. Than by defition (x, y) are in the inversion set.

Step: Assume i and j are k elements apart and we prove the statement for i and j at distance $k + 1$. Assume by contradiction that $A[i + k]$ is not an inversion, therfor it is larger than any element that came before it - in particular $A[i]$, For otherwise it would be an inversion. If $A[i + k]$ is larger than $A[j]$ than the pair $(A[i + k], A[j])$ is an inversion for j and i are at distance $k + 1$. If $A[k + i]$ is smaller than $A[j]$ than the pair $(A[i + k], A[i])$ is an inversion since $A[i] > A[j] > A[i + k]$ by the assumption the $(A[i], A[j]) = (x, y)$ is in the inversion set. $\square$

By the Lemma any element between $A[i]$ and $A[j]$ are in the inversion set, that means that in the inner loop of *InsertionSort* all of those elements will be switched in the inner loop, including (x, y).

Conclusion: The number of elements in the inversion set of A is precisly the number of iterations of the inner loop of *InsertionSort*. In other words, the run time of *InsertionSort* is $\Theta(|S|)$.

5.1-2

Algorithm 5 Random(a,b)

---
if $a = b$ **then**
   a
end if
while $a < b$ **do**
  if $Random(0, 1) > 0$ **then**
     $Random(a, \frac{a+b}{2})$
  else
     $Random(\frac{a+b}{2}, b)$
  end if
end while

The runtime of the above algorithm is $O(log(\frac{b-a}{2}))$.

6.1-1   The maximum number of elements in a heap of height h is $2^0 + 2^1 + ... + 2^h = \sum_{i=1}^{h} 2^i = \frac{2^{h+1}-1}{2-1} = 2^{h+1} - 1$. The minimum number

of elements occures when there is percisly one leaf node (i.e. the bottom level of the binary-tree is empty but one element), meaning:

$$2^0 + 2^1 + ...2^{h-1} + 2 = \sum_{i=0}^{h-1} 2^i + 1 = \frac{2^h - 1}{2 - 1} + 1 = 2^h$$

6.1-2   Proof by Induction:

Base: $n = 1$, A single node heap is at height $0 = log(1) = log(n)$

Step: We assume the statement is correct for $n = k - 1$ and prove for a heap of size $n = k$. Consider the last element of the heap $A[k]$, by the definition of the heap, its parent is the element $A[\frac{k}{2}]$. By the induction step the heap $A[1...\frac{k}{2}]$ is of height $log(\frac{k}{2}) = log(k) - log(2) = log(k) - 1$. Thus, the height of the heap $A[1...k]$ has one more layer than $A[1...\frac{k}{2}]$, that is $log(k)$.
$\square$
